FAN5365 1A / 0.8A, 6MHz Digitally Programmable Regulator

Features

- High Efficiency (>88%) at 6MHz
- 800mA or 1A Output Current
- Regulation Maintained with V_{IN} from 2.3V to 5.5V
- 6-Bit V_{OUT} Programmable from 0.75 to 1.975V
- 6MHz Fixed-Frequency Operation (PWM Mode)
- Excellent Load and Line Transient Response
- Small Size, 470nH Inductor Solution
- ±2% DC Voltage Accuracy in PWM Mode
- 25ns Minimum On-Time
- High-Efficiency, Low-Ripple, Light-Load PFM
- Smooth Transition between PWM and PFM
- 40µA Operating PFM Quiescent Current
- I²C™-Compatible Interface up to 3.4Mbps
- Pin-Selectable or I²C[™] Programmable Output Voltage
- 9-Bump, 1.27 x 1.29mm, 0.4mm Pitch WLCSP Package

Applications

- 3G, WiFi[®], WiMAX[™], and WiBro[®] Data Cards
- Netbooks[®], Ultra-Mobile PCs
- SmartReflex[™]-Compliant Power Supply
- Split Supply DSPs and μP Solutions OMAP™, XSCALE™
- Handset Graphic Processors (NVIDIA®, ATI)

Description

The FAN5365 is a high-frequency, ultra-fast transient response, synchronous step-down, DC-DC converter optimized for low-power applications using small, low-cost inductors and capacitors. The FAN5365 supports up to 800mA or 1A load current.

The FAN5365 is ideal for mobile phones and similar portable applications powered by a single-cell Lithium-lon battery. With an output voltage range adjustable via I^2C^{TM} interface from 0.75V to 1.975V, it supports low-voltage DSPs and processors, core power supplies, and memory modules in smart phones, data cards, and hand-held computers.

The FAN5365 operates at 6MHz (nominal) fixed switching frequency in PWM mode.

During light-load conditions, the regulator includes a PFM mode to enhance light-load efficiency. The regulator transitions smoothly between PWM and PFM modes with no glitches on V_{OUT} . In hardware shutdown, the current consumption is reduced to less than 200nA.

The serial interface is compatible with fast / standard mode, fast mode plus, and high-speed mode I²C specifications, allowing transfers up to 3.4Mbps. This interface is used for dynamic voltage scaling with 12.5mV voltage steps, for reprogramming the mode of operation (PFM or forced PWM), or to disable/enable the output voltage.

The chip's advanced protection features include short-circuit protection and current and temperature limits. During a sustained over-current event, the IC shuts down and restarts after a delay to reduce average power dissipation into a fault.

During startup, the IC controls the output slew rate to minimize input current and output overshoot at the end of soft-start. The IC maintains a consistent soft-start ramp, regardless of output load during startup.

The FAN5365 is available in a 1.27 x 1.29mm, 9-bump WLCSP package.

All trademarks are the property of their respective owners

Ordering Information

Part Number ⁽¹⁾	Option	Slave	Slave Address LSB		Output Current			Power-up Defaults		Package
		A2	A 1	Α0	mA	Min.	Max.	VSEL0	VSEL1	
FAN5365UC00X	00	0	1	0	800	0.7500	1.4375 ⁽³⁾	1.05	1.20	WLCSP-09
FAN5365UC02X	02	1	1	0	800	0.7500	1.4375 ⁽³⁾	0.95	1.10	WLCSP-09
FAN5365UC03X ⁽²⁾	03	0	0	0	1000	0.7500	1.5375	1.00	1.20	WLCSP-09
FAN5355UC06X ⁽²⁾	06	0	0	0	1000	1.1875	1.9750	1.80	1.80	WLCSP-09

Notes

- 1. The "X" designator on the part number indicates tape and reel packaging.
- 2. Preliminary; not full production release at this time. Contact a Fairchild representative for information.
- 3. V_{OUT} is limited to the maximum voltage for all VSEL codes greater than the maximum V_{OUT} listed.

Typical Application

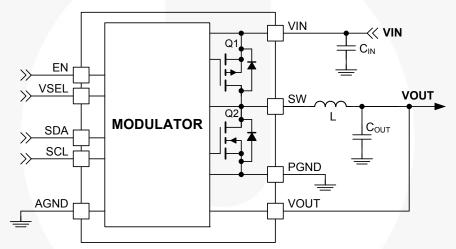

Figure 1. Typical Application

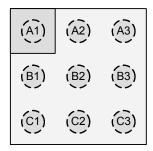

Table 1. Recommended External Components

Component	Description	Vendor	Parameter	Min.	Тур.	Max.	Units
1 (1)	470nH Nominal	Murata, TDK, FDK	L ⁽⁴⁾	390	470	600	nΗ
L (LOUT)	L (L _{OUT}) 470nH Nominal		DCR (Series R)	1.9	80		mΩ
C _{OUT} ⁽⁵⁾	0603 (1.6x0.8x0.8), 10μF X5R	Various	C ⁽⁶⁾	2.2	10.0	15.0	μF
C _{IN}	0402 (1x0.5x0.25), 4.7μF X5R	Taiyo-Yuden		1.6	4.7		μF

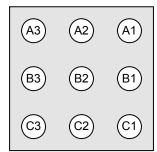

Notes:

- 4. Minimum L incorporates tolerance, temperature, and partial saturation effects (L decreases when increasing current).
- A capacitor similar to C_{IN} can be used for C_{OUT}. With 1.4V of bias, a 4.7μF 0402 capacitor minimum value is 2.5μF.
 The regulator is stable, but transient response degraded due to large signal effects.
- 6. Minimum C is a function of initial tolerance, maximum temperature, and the effective capacitance being reduced due to frequency, dielectric, and voltage bias effects. C_{IN} is biased with a higher voltage which reduces its effective capacitance by a larger amount.

Pin Configuration

Bumps Facing Down

Bumps Facing Up

Figure 2. WLCSP-09, 0.4mm Pitch

Pin Definitions

Pin#	Name	Description
A1	VSEL	Voltage Select . When HIGH, V _{OUT} is set by VSEL1. When LOW, V _{OUT} is set by VSEL0. This behavior can be overridden through I ² C register settings. This pin should not be left floating.
A2	VIN	Input Voltage . Connect to input power source. The connection from this pin to C_{IN} should be as short as possible.
А3	SDA	SDA. I ² C interface serial data. This pin should not be left floating.
B1	SW	Switching Node. Connect to output inductor.
B2	SCL	SCL. I ² C interface serial clock. This pin should not be left floating.
В3	EN	Enable . When this pin is HIGH, the circuit is enabled. When LOW, part enters shutdown mode and input current is minimized. This pin should not be left floating.
C1	VOUT	Output Voltage Monitor. Tie this pin to the output voltage at C _{OUT} . This is a signal input pin to the control circuit and does not carry DC current.
C2	PGND	Power GND . Power return for gate drive and power transistors. Connect to AGND on PCB. The connection from this pin to the bottom of C_{IN} should be as short as possible.
C3	AGND	Analog GND . This is the signal ground reference for the IC. All voltage levels are measured with respect to this pin. AGND should be connected to PGND at a single point.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Par	ameter		Min.	Max.	Units
	VIN, SW Pins			-0.3	6.5	
V_{CC}	V _{OUT}			-0.3	2.5	V
	Other Pins			-0.3	$V_{IN} + 0.3^{(7)}$	
ESD	Floatroatatio Discharge Protection	Human Body Model, JESD22-A	114	3		KV
ESD	Electrostatic Discharge Protection	Charged Device Model, JESD22	2-C101		1	ΚV
TJ	Junction Temperature			-4 0	+150	°C
T _{STG}	Storage Temperature			-65	+150	°C
T _L	Lead Soldering Temperature, 10 Sec	onds			+260	°C

Note:

Lesser of 6.5V or V_{CC}+0.3V.

Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to absolute maximum ratings.

Symbol	Parameter	Min.	Max.	Units
V _{IN}	Supply Voltage	2.3	5.5	V
V _{CCIO}	SDA and SCL Voltage Swing ⁽⁸⁾	1.2	2.0	V
T _A	Ambient Temperature	-4 0	+85	°C
TJ	Junction Temperature	-40	+125	°C

Note:

8. The I²C interface operates with t_{HD;DAT} = 0 as long as the pull-up voltage for SDA and SCL is less than 2.5V. If voltage swings greater than 2.5V are required (for example, if the I²C bus is pulled up to V_{IN}), the minimum t_{HD;DAT} must be increased to 80ns. Most I²C masters change SDA near the midpoint between the falling and rising edges of SCL, which provides ample t_{HD;DAT}.

Dissipation Ratings⁽⁹⁾

Package	R _{0JA} ⁽¹⁰⁾	Power Rating at T _A ≤ 25°C	Derating Factor > T _A = 25°C
Wafer-Level Chip-Scale Package (WLCSP)	110°C/W	900mW	9mW/°C

Notes:

- 9. Maximum power dissipation is a function of $T_{J(max)}$, θ_{JA} , and T_A . The maximum allowable power dissipation at any allowable ambient temperature is $P_D = [T_{J(max)} T_A] / \theta_{JA}$.
- 10. This thermal data is measured with a high-K board (four-layer board, according to the JESD51-7 JEDEC standard).

Electrical Specifications

Unless otherwise noted, over the recommended operating range for V_{IN} and T_{A} , EN = VSEL = SCL = SDA = 1.8V, and register VSEL0[6] bit = 1. Typical values are at $V_{IN} = 3.6V$, $T_{A} = 25^{\circ}C$. Circuit and components according to Figure 1.

Circuit Description

The FAN5365 is a synchronous buck regulator that typically operates at 6MHz with moderate to heavy load currents. At light load currents, the converter operates in power-saving PFM mode. The regulator automatically transitions between fixed-frequency PWM mode and variable-frequency PFM mode to maintain the highest possible efficiency over the full range of load current.

The FAN5365 uses a very fast, non-linear control architecture to achieve excellent transient response with minimum-sized external components.

The FAN5365 integrates an I²C-compatible interface, allowing transfers up to 3.4Mbps. This communication interface can be used to:

- Dynamically re-program the output voltage in 12.5mV increments
- Reprogram the mode of operation to enable or disable PFM mode
- Control voltage transition slew rate
- Enable / disable the regulator.

For more details, refer to the ${}^{\hat{r}}C$ Interface and Register Description sections.

Output Voltage Programming

V_{OUT} is programmed according to the following equations:

Option ⁽¹²⁾	V _{OUT} Equation				
00, 02, 03	$V_{OUT} = 0.75 + N_{VSEL} \bullet 12.5 mV$	(1)			
06	V _{OUT} = 1.1875 + N _{VSEL} • 12.5mV	(2)			

Note:

12. For option 00 and 02, the maximum voltage is 1.4375V.

Table 2. V_{SEL} vs. V_{OUT}

Power-Up, EN, and Soft-Start

All internal circuits remain de-biased and the IC is in a very low quiescent current state until the following are true:

- V_{IN} is above its rising UVLO threshold, and
- EN is HIGH.

At that point, the IC begins a soft-start cycle, its I²C interface is enabled, and its registers are loaded with their default values.

During the initial soft-start, V_{OUT} ramps linearly to the setpoint programmed in the VSEL register selected by the VSEL pin. The soft-start features a fixed output voltage slew rate of 20V/ms and achieves regulation approximately $90\mu s$ after EN rises. PFM mode is enabled during soft-start until the output is in regulation, regardless of the MODE bit settings. This allows the regulator to start into a partially charged output without discharging it; in other words, the regulator does not allow current to flow from the load back to the battery.

As soon as the output has reached its setpoint, the control forces PWM mode for about $85\mu s$ to allow all internal control circuits to calibrate.

Table 3. Soft-Start Timing

Symbol	Description	Value (μs)
tssdly	Time from EN to start of soft- start ramp	100
t _{REG}	V _{OUT} ramp start to regulation	(VSEL-0.1) X 53
t _{POK}	PWROK (CONTROL2[5]) rising from t _{REG}	11
t _{CAL}	Regulator stays in PWM mode during this time	10

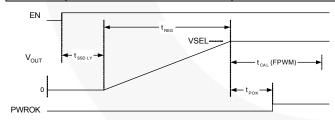

Figure 35. Soft-Start Timing

Table 4. EN_DCDC Behavior

EN_DCDC Bit	EN Pin	I ² C	REGULATOR
0	0	OFF	OFF
1	1	ON	ON
1	0	OFF	OFF
0	1	ON	OFF

Software Enable

The EN_DCDC bit, VSELx[7], can be used to enable the regulator in conjunction with the EN pin. Setting EN_DCDC with EN HIGH begins the soft-start sequence described above.

Light-Load (PFM) Operation

The FAN5365 provides a low ripple, single-pulse, PFM mode that ensures:

- Smooth transitions between PFM and PWM modes
- Single-pulse operation for low ripple
- Predictable PFM entry and exit currents.

PFM begins after the inductor current has become discontinuous, crossing zero during the PWM cycle for 32 consecutive cycles. PFM exit occurs when discontinuous current mode (DCM) operation cannot supply sufficient current to maintain regulation. During PFM mode, the inductor current ripple is about 40% higher than in PWM mode. The load current required to exit PFM mode is thereby about 20% higher than the load current required to enter PFM mode, providing sufficient hysteresis to prevent "mode chatter."

While PWM ripple voltage is typically less than $4mV_{P-P}$, PFM ripple voltage can be up to $30mV_{P-P}$ during very light load. To prevent significant undershoot when a load transient occurs, the initial DC setpoint for the regulator in PFM mode is set 10mV higher than in PWM mode. This offset decays to about 5mV after the regulator has been in PFM mode for $\sim 100 \, \mu s$. The maximum instantaneous voltage in PFM is 30mV above the setpoint.

PFM mode can be disabled by writing to the mode control bits: CONTROL1[3:0] (see Table 5)

Output Voltage Transitions

The IC regulates V_{OUT} to one of two setpoint voltages, as determined by the VSEL pin and the HW_nSW bit.

Table 5. V_{OUT} Setpoint and Mode Control MODE_CTRL, CONTROL1[3:2] = 00

VSEL Pin	HW_nSW Bit	V _{OUT} Setpoint	PFM
0	1	VSEL0	Allowed
1	1	VSEL1	Per MODE1
Х	0	VSEL1	Per MODE1

If $HW_nSW = 0$, V_{OUT} transitions are initiated through the following sequence:

- Write the new setpoint in VSEL1.
- Write desired transition rate in DEFSLEW, CONTROL2[2:0], and set the GO bit in CONTROL2[7].

If $HW_nSW = 1$, V_{OUT} transitions are initiated either by changing the state of the VSEL pin or by writing to the VSEL register selected by the VSEL pin.

Positive Transitions

When transitioning to a higher V_{OUT} , the regulator can perform the transition using multi-step or single-step mode.

Multi-Step Mode:

The internal DAC is stepped at a rate defined by DEFSLEW, CONTROL2[2:0], ranging from 000 to 110. This mode minimizes the current required to charge C_{OUT} and thereby minimizes the current drain from the battery when transitioning. The PWROK bit, CONTROL2[5], remains LOW until about 1.5 μ s after the DAC completes its ramp.

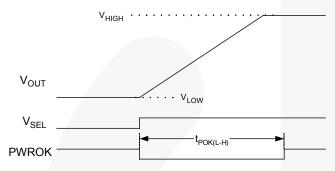

Figure 36. Multi-Step Vout Transition

Single-Step Mode:

Used if DEFSLEW, CONTROL2[2:0] = 111. The internal DAC is immediately set to the higher voltage and the regulator performs the transition as quickly as its current limit circuit allows, while avoiding excessive overshoot.

Figure 37 shows single-step transition timing. $t_{V(L-H)}$ is the time it takes the regulator to settle to within 2% of the new setpoint, typically 7 μ s for a full-range transition. The PWROK bit, CONTROL2[5], goes LOW until the transition is complete and V_{OUT} settled. This typically occurs ~2 μ s after $t_{V(L-H)}$.

It is good practice to reduce the load current before making positive V_{SEL} transitions. This reduces the time required to make positive load transitions and avoids current–limit-induced overshoot.

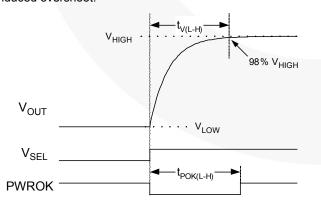

Figure 37. Single-Step Vout Transition

All positive V_{OUT} transitions inhibit PFM until the transition is complete, which occurs at the end of $t_{POK(L-H)}$.

Negative Transitions

When moving from V_{SEL} = 1 to V_{SEL} = 0, the regulator enters PFM mode, regardless of the condition of the MODE bits, and remains in PFM until the transition is complete. Reverse current through the inductor is blocked, and the PFM minimum frequency control inhibited, until the new setpoint is reached; at which time, the regulator resumes control using the mode established by MODE_CTRL. The transition time from V_{HIGH} to V_{LOW} is controlled by load current and output capacitance as:

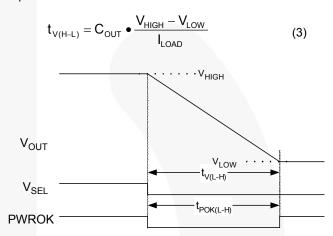

Figure 38. Negative V_{OUT} Transition

Protection Features

Current Limit / Auto-Restart

The regulator includes cycle-by-cycle current limiting, which prevents the instantaneous inductor current from exceeding the "PMOS Current Limit" threshold.

The IC enters "fault" mode after sustained over-current. If current limit is asserted for more than 32 consecutive cycles (about $20\mu s$), the IC returns to shutdown state and remains in that condition for $\sim\!80\mu s$. After that time, the regulator attempts to restart with a normal soft-start cycle. If the fault has not cleared, it shuts down $\sim\!20\mu s$ later.

If the fault is a short circuit, the initial current limit is $\sim 30\%$ of the normal current limit, which produces a very small drain on the system power source.

Thermal Protection

When the junction temperature of the IC exceeds 150°C, the device turns off all output MOSFETs and remains in a low quiescent current state until the die cools to 130°C before starting a normal soft-start cycle.

Under-Voltage Lockout (UVLO)

The IC turns off all MOSFETs and remains in a low quiescent current state until V_{IN} rises above the UVLO threshold.

I²C Interface

The FAN5365's serial interface is compatible with standard, fast, fast plus, and high-speed mode I²C bus specifications. The FAN5365's SCL line is an input and its SDA line is a bi-directional open-drain output; it can only pull down the bus when active. The SDA line only pulls LOW during data reads and when signaling ACK. All data is shifted in MSB (bit 7) first.

Slave Address

In Table 6, A1 and A0 are according to the Ordering Information table on page 2.

Table 6. I²C Slave Address

7	6	5	4	3	2	1	0
1	0	0	1	A2	A1	A0	R/W

In Hex notation, the slave address assumes a 0 LSB. For example, the hex slave address of option 00 is 94H.

Register Addressing

FAN5365 has four user-accessible registers:

Table 7. I²C Register Address

		Address											
	7	6	5	4	3	2	1	0					
VSEL0	0	0	0	0	0	0	0	0					
VSEL1	0	0	0	0	0	0	0	1					
CONTROL1	0	0	0	0	0	0	1	0					
CONTROL2	0	0	0	0	0	0	1	1					

Bus Timing

As shown in Figure 39, data is normally transferred when SCL is LOW. Data is clocked in on the rising edge of SCL. Typically, data transitions shortly at or after the falling edge of SCL to allow ample time for the data to set up before the next SCL rising edge.

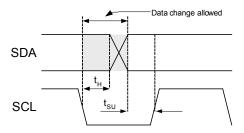

Figure 39. Data Transfer Timing

Each bus transaction begins and ends with SDA and SCL HIGH. A transaction begins with a "START" condition, which is defined as SDA transitioning from 1 to 0 with SCL HIGH, as shown in Figure 40.

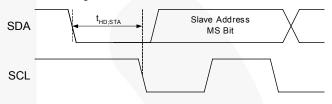

Figure 40. Start Bit

A transaction ends with a "STOP" condition, which is defined as SDA transitioning from 0 to 1 with SCL HIGH, shown in Figure 41.

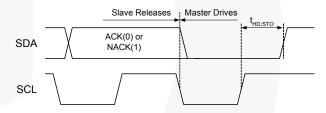

Figure 41. Stop Bit

During a read from the FAN5365 (Figure 44), the master issues a "Repeated Start" command after sending the register address and before resending the slave address. The "Repeated Start" is a 1-to-0 transition on SDA while SCL is HIGH, as shown in Figure 42.

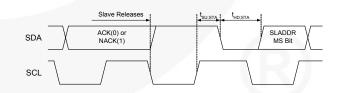

Figure 42. Repeated Start Timing

High-Speed (HS) Mode

The protocols for High-Speed (HS), Low-Speed (LS), and Fast-Speed (FS) modes are identical, except the bus speed for HS mode is 3.4MHz. HS mode is entered when the bus master sends the HS master code 00001XXX after a start condition. The master code is sent in Fast or Fast Plus mode (less than 1MHz clock) and slaves do not acknowledge (ACK) this transmission.

The master then generates a repeated start condition (Figure 42) that causes all slaves on the bus to switch to HS mode. The master then sends I²C packets, as described above, using the HS mode clock rate and timing.

The bus remains in HS mode until a stop bit (Figure 41) is sent by the master. While in HS mode, packets are separated by repeated start conditions.

Read and Write Transactions

The following figures outline the sequences for data read and write. Bus control is signified by the shading of the packet, defined as Master Drives Bus and Slave Drives Bus. All addresses and data are MSB first.

Table 8. I²C Bit Definitions for Figure 43 and Figure 44

Symbol	Definition
S	START, Figure 40.
А	ACK. The slave drives SDA to 0 to acknowledge the preceding packet.
Ā	NACK. The slave sends a 1 to NACK the preceding packet.
R	Repeated START, see Figure 42.
Р	STOP, see Figure 41.

Table 10. Bit Type Definitions for Table 9

#	Active Bit	Changing this bit changes the behavior of the converter, as described below.
#	Disabled	Converter logic ignores changes made to this bit. Bit can be written and read-back.
#	Read-Only	Writing to this bit through I ² C does not change the read-back value, nor does it change converter behavior.

Bit Definitions

Table 11 defines the operation of each register bit. Superscript characters define the default state for each option. Superscripts 0,2,3,6 signify the default values for

options 00, 02, 03, and 06, respectively. $^{\rm A}$ signifies the default for all options.

Layout Recommendations

FAN5365 switches at a relatively high frequency of 6MHz; thus the recommended layout should be followed carefully as additional parasitic effects caused by moving components further away or routing through internal layers can cause issues. In addition, possible detrimental effects to regulator performance EMI issues can be generated by introducing unintentional coupling paths in the layout.

To minimize VIN and SW spikes and thereby reduce voltage stress on the IC power switches; it is critical to minimize the loop length for the VIN bypass capacitor. $C_{\rm IN}$ must be placed

next to the IC with routing on the top layer, as shown in Figure 45 and Figure 46.

Switching current paths through C_{IN} and C_{OUT} should be returned directly to the GND bumps of the IC on the top layer of the printed circuit board (PCB).

The SW node should be treated as a noisy signal and separated by the ground plane or "keepout region" from any sensitive signals in the system. Routing sensitive high-impedance voltage reference signals should be avoided on the layer directly beneath the SW node.

DISCLAIMER

FAIRCHILD SEMICONDUCTOR RESERVES THE RIGHT TO MAKE CHANGES WITHOUT FURTHER NOTICE TO ANY PRODUCTS HEREIN TO IMPROVE RELIABILITY, FUNCTION, OR DESIGN. FAIRCHILD DOES NOT ASSUME ANY LIABILITY ARISING OUT OF THE APPLICATION OR USE OF ANY PRODUCT OR CIRCUIT DESCRIBED HEREIN; NEITHER DOES IT CONVEY ANY LICENSE UNDER ITS PATENT RIGHTS, NOR THE RIGHTS OF OTHERS. THESE SPECIFICATIONS DO NOT EXPAND THE TERMS OF FAIRCHILD'S WORLDWIDE TERMS AND CONDITIONS, SPECIFICALLY THE WARRANTY THEREIN, WHICH COVERS THESE PRODUCTS

LIFE SUPPORT POLICY

FAIRCHILD'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF FAIRCHILD SEMICONDUCTOR CORPORATION.

As used herein:

- 1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user
- 2. A critical component in any component of a life support, device, or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

ANTI-COUNTERFEITING POLICY

Fairchild Semiconductor Corporation's Anti-Counterfeiting Policy, Fairchild's Anti-Counterfeiting Policy is also stated on our external website, www.fairchildsemi.com, under Sales Support.

Counterfeiting of serriconductor parts is a growing problem in the industry. All manufacturers of semiconductor products are experiencing counterfeiting of their parts. Customers who inadvertently purchase counterfeit parts experience many problems such as loss of brand reputation, substandard performance, failed applications, and increased cost of production and manufacturing delays. Fairchild is taking strong measures to protect ourselves and our customers from the proliferation of counterfeit parts. Fairchild strongly encourages customers to purchase Fairchild parts either directly from Fairchild or from Authorized Fairchild Distributors who are listed by country on our web page cited above. Products customers buy either from Fairchild directly or from Authorized Fairchild Distributors are genuine parts, have full traceability, meet Fairchild's quality standards for handling and storage and provide access to Fairchild's full range of up-to-date technical and product information. Fairchild and our Authorized Distributors will stand behind all warranties and will appropriately address any warranty issues that may arise. Fairchild will not provide any warranty coverage or other assistance for parts bought from Unauthorized Sources. Fairchild is committed to combat this global problem and encourage our customers to do their part in stopping this practice by buying direct or from authorized distributors.

PRODUCT STATUS DEFINITIONS

Definition of Terms
